(54) Title: INHIBITING OF EROSION OF VESSELS

(57) Abstract

A method of inhibiting erosion of an interior surface of a process vessel by solid objects carried in a fluid passing over the interior surface includes providing at least one formation at or in close proximity to the interior surface to interfere with the flow of the fluid over the interior surface, and to interfere with the movement of the solid objects by the fluid. The invention extends to a process vessel (10) which includes a body (16) defining an interior vessel surface (20), a catalyst bed (12) in the body (16), retaining means (22) on the catalyst bed for retaining the catalyst bed in position, and at least one formation (26) at or in close proximity to the interior vessel surface above the retaining means for interfering with fluid flow above the retaining means.

INHIBITING OF EROSION OF VESSELS

THIS INVENTION relates to the inhibiting of erosion of vessels. In particular, it relates to a method of inhibiting erosion of an interior surface of a process vessel, such as an interior refractory surface of a reformer, to a process vessel and to a 5 method of converting a reformer.

According to a first aspect of the invention, there is provided a method of inhibiting erosion of an interior surface of a process vessel by solid objects carried in a fluid passing over the interior surface, the method including providing at least one formation at or in close proximity to the interior surface to interfere with the 10 flow of the fluid over the interior surface; and to interfere with the movement of the solid objects by the fluid.

The formation may, for example, deflect the solid objects away from the interior surface or trap the solid objects.

At least a portion of the interior surface of the vessel may be substantially cylindrical, and the fluid may follow a whirling flow path. Thus, the method may include providing a plurality of circumferentially spaced formations at or in close proximity to an annular portion or zone of the interior surface expected to be most 5 affected by erosion. The formations may be provided in a horizontal plane and may be equidistantly spaced.

The process vessel may be a reformer for producing synthesis gas, e.g. an autothermal or secondary reformer.

10 The objects may be trapped in bays or pockets defined between pairs of formations or between each formation and the interior surface of the vessel, as the case may be.

15 According to a second aspect of the invention, there is provided a method of inhibiting erosion of an interior refractory surface of a reformer for producing synthesis gas, by solid objects carried in a gas stream passing over the interior refractory surface, the method including providing at least one formation at or in close proximity to the refractory surface in the path of the objects to interfere with the flow of the gas over the interior surface, and to interfere with the movement of the solid objects by the gas.

20 A plurality of formations may be provided. Each formation may trap the solid objects, the objects being trapped in bays or pockets defined between pairs of formations or between each formation and the interior refractory surface, as the case may be.

25 Typically, the reformer includes a catalyst bed with retaining means on the catalyst bed for retaining the catalyst bed in position in the face of high gas velocities in the reformer. The retaining means may be a generally horizontally extending tile or brick layer, the tiles or bricks being configured to allow gas to

pass downwardly through the tile or brick layer. Pieces of refractory lining above the tile or brick layer and sometimes pieces of the tiles or bricks can, however, in use break loose and can then be whirled around the inner periphery of the reformer in an annular zone above the tile or brick layer by the gas flowing through the reformer, particularly in reformers converted to include an open flame reaction zone above the catalyst bed, and to reformers operated at higher gas throughput than originally designed for. These solid objects erode the refractory surface in an annular band or zone extending for a short distance, e.g. 30cm, above an upper surface of the tile or brick layer.

5 10 Preferably, the method includes providing a plurality, e.g. six, formations at or in close proximity to the interior refractory surface and above the upper surface of the tile or brick layer so that the formations are located within the whirling flow path of the solid objects.

15 In one embodiment of the invention, providing a plurality of formations includes placing a plurality of tiles or bricks, e.g. six, each having an increased depth or thickness compared to other tiles or bricks in the layer of tiles or bricks, at spaced peripheral positions in the layer of tiles or bricks, adjacent the interior refractory surface. Typically, the tiles or bricks of increased depth or thickness are equidistantly spaced.

20 25 According to a third aspect of the invention, there is provided a process vessel which includes

a body defining an interior vessel surface;

a catalyst bed in the body;

retaining means on the catalyst bed for retaining the catalyst bed in

position; and

at least one formation at or in close proximity to the interior vessel surface above the retaining means for interfering with fluid flow above the retaining

means, which fluid flow can cause fluid-borne solid objects in said flow to erode the interior vessel surface above the retaining means.

The or each formation may be arranged to deflect the solid objects away from the interior surface. Typically, the or each formation is however arranged to trap the 5 solid objects.

The process vessel may be a reformer for the production of synthesis gas. The retaining means may include a generally horizontally extending layer of tiles or bricks laid on top of the catalyst bed, the layer of tiles or bricks allowing fluid to pass downwardly through the layer. The vessel may include a plurality e.g. six, 10 spaced formations for interfering with fluid flow above the layer of tiles or bricks. Each formation may be defined by a tile or brick in the layer having an increased depth or thickness compared to the depth or thickness of other tiles or bricks in the layer. The tiles or bricks of increased depth or thickness may be located at circumferentially equidistantly spaced peripheral positions in the layer of tiles or 15 bricks, and each tile or brick of increased depth may act to trap the gas-borne solid objects in a bay or pocket defined between the brick or tile of increased depth and the interior vessel surface, or between two such bricks or tiles.

Each tile or brick may be polygonal in outline in plan view, e.g. hexagonal or part-hexagonal in plan view. Thus, some of the tiles or bricks may be regular 20 hexagonal in plan view, some may be trapezoidal and half of a regular hexagon in plan view, and some may be pentagonal shaped in plan view to allow the tiles or bricks to be laid out next to one another in abutting side by side relationship in a horizontal plane to form a roughly hexagonal plane figure in outline in plan view having extremities which fall on the outline of a hexagon and a circle.

25 At least some of the bricks or tiles may include a plurality of passages extending therethrough between an opening in a top surface and an opening in a bottom surface of each of said some bricks or tiles. At least 15% of a top surface area

of each apertured brick or tile may be occupied by the openings of the passages. Preferably, the percentage of the top surface area of each apertured brick or tile occupied by the openings is at least 20%, e.g. 21 %. Typically, however, at least some, e.g. seven, centrally located bricks or tiles have no passages.

5 A ratio between the depth or thickness of the bricks or tiles having an increased depth or thickness to the depth or thickness of the other bricks or tiles in the layer may be between 1,5:1 and 2:1. Preferably, the ratio is between 1,8:1 and 1,9:1. In one embodiment, the ratio is between 1,82:1 and 1,84:1, e.g. 1,83:1.

10 Examples of suitable materials for the bricks or tiles are high purity alumina (Al_2O_3) brick or calcium bonded tabular alumina castable with an alumina content of greater than 96% by weight.

15 According to a fourth aspect of the invention, there is provided a method of converting a reformer for production of synthesis gas having a catalyst bed but no open flame reaction zone above the catalyst bed, to a reformer having a catalyst bed and an open flame reaction zone above the catalyst bed, the method including providing at least one formation at or in close proximity to an interior refractory surface of the reformer at an elevation at which erosion of the refractory surface of the converted reformer due to gas-borne solid objects is expected, the formation acting to interfere with the flow of the gas over the 20 interior surface, and to interfere with the movement of the solid objects by the gas.

This interference may act, for example, to deflect the solid objects away from the interior vessel surface, or to trap the solid objects.

Preferably, the formation is configured to trap the gas-borne solid objects.

The reformer may include retaining means on the catalyst bed for retaining the catalyst bed in position. The formation may be provided so that it interferes with the movement of solid objects expected to be carried by the gas in a whirling flow path above the retaining means.

- 5 The retaining means may include a layer of bricks or tiles laid on top of the catalyst bed. The method may include replacing at least some of the existing bricks or tiles in the layer with replacement bricks or tiles which are larger in plan view and/or which are heavier, compared to the existing bricks or tiles in the layer.
- 10 Preferably, the method includes providing a plurality of formations at or in close proximity to the interior refractory surface of the reformer at the elevation at which erosion of the refractory surface due to gas-borne solid objects is expected. Each formation may be defined by a brick or tile in the layer having an increased depth or thickness compared to the depth or thickness of other tiles or bricks in the layer. The bricks or tiles and the layer of bricks or tiles may thus be as hereinbefore described.
- 15
- 20 The tiles or bricks of increased depth or thickness may thus be located at circumferentially equidistantly spaced peripheral positions in the layer of tiles or bricks.
- 25 All of the existing bricks or tiles in the layer may be replaced with replacement bricks or tiles. Some of the replacement bricks or tiles may be regular hexagonal in plan view, some of the replacement bricks or tiles may be trapezoidal and half of a regular hexagon in plan view, and some of the replacement bricks or tiles may be pentagonal shaped in plan view, allowing the replacement bricks or tiles to be laid out next to one another in abutting side by side relationship in a horizontal plane to form a roughly hexagonal plane figure in outline in plan view

having extremities which fall on the outline of a hexagon and a circle, as hereinbefore described.

Each replacement brick or tile of standard depth may have the same nominal diameter, a ratio between the nominal diameter and a thickness or depth of each replacement brick or tile of standard depth being between 4:1 and 1:1. Preferably, the ratio between the nominal diameter and the thickness or depth of these replacement bricks or tiles are between 3:1 and 2:1, e.g. 2,5:1. By nominal diameter is meant the diameter of a circle on which the extremities of each replacement brick or tile fall in plan view.

10 The invention will now be described, by way of example, with reference to the accompanying diagrammatic drawings, in which

Figure 1 shows a partially sectioned side elevational view of a reformer converted in accordance with the invention;

15 Figure 2 shows a top plan view of a brick or tile layer of the reformer of Figure 1;

Figure 3 shows a top plan view of a hexagonal brick or tile of the brick or tile layer of Figure 2;

20 Figure 4 shows a sectioned side view of the brick or tile of Figure 3 taken at IV-IV in Figure 3;

Figure 5 shows a top plan view of a pentagonal brick or tile of the brick or tile layer of Figure 2;

25 Figure 6 shows a sectioned side view of the brick or tile of Figure 5 taken at VI-VI in Figure 5;

Figure 7 shows a top plan view of a half hexagonal brick or tile of the brick or tile layer of Figure 2; and

Figure 8 shows a sectioned side view of the brick or tile of Figure 7, taken at VIII-VIII in Figure 7.

Referring to Figure 1 of the drawings, reference numeral 10 generally indicates a vertically orientated reformer converted in accordance with the invention. The 5 reformer 10 is suitable for the production of synthesis gas and has been converted from having a catalyst bed 12 but no open flame reaction zone above the catalyst bed 12, to having the catalyst bed 12 and an open flame reaction zone 14 above the catalyst bed 12.

10 The reformer 10 includes a body 16 which includes a refractory layer 18 defining an interior vessel surface 20. Retaining means, in the form of a horizontally extending brick or tile layer 22, rests on the catalyst bed 12 for retaining the catalyst bed 12 in position in use. The reformer 10 has an internal diameter of 2,104m.

15 With reference to Figure 2 of the drawings, the brick or tile layer 22 forms a roughly hexagonal plane figure in outline in plan view, having extremities in the form of rounded or bevelled corners which fall on the outline of a hexagon, as well as on the outline of a circle. The layer 22 comprises thirty tiles or bricks 24 which are regular hexagonal in plan view, six tiles or bricks 26 which are pentagonal in plan view and twelve tiles or bricks 28 which are a trapezoidal half 20 of a hexagon in plan view. As shown in Figure 2 of the drawings, the tile or brick layer 22 substantially spans the interior of the reformer 10.

25 The pentagonal tiles or bricks 26 are located at positions corresponding to the six rounded corners of the hexagonal layer 22 defined by the tiles or bricks 24, 26, 28. The tiles or bricks 26 are thus located at circumferentially equidistantly spaced peripheral positions in the layer 22 of tiles or bricks, in close proximity to the interior vessel surface 20 defined by the refractory layer 18. An expansion

gap (not shown) of 21mm is provided between each brick or tile 26 and the interior vessel surface 20.

5 Each hexagonal brick or tile 24 has a nominal diameter of 300mm and a thickness or depth of 120mm. Thus, a ratio between the diameter and the depth of each brick or tile 24 is 2,5:1. Nineteen circular cylindrical passages 30 extend respectively between openings in a top surface and openings in a bottom surface in each brick or tile 24 (not shown in Figure 2). The centres of the passages 30 are spaced 55mm apart from each other. Thus, the passages are arranged in a regular hexagonal layout. The percentage of the top surface area of each 10 apertured brick or tile 24 occupied by the openings of the passages 30 is 25,8%. However, seven centrally located regular hexagonal tiles or bricks 32 do not have any passages extending through them.

15 Referring to Figure 6 of the drawings, and comparing Figure 6 to Figures 4 and 8 of the drawings, it is apparent that the pentagonal tiles or bricks 26 are deeper or thicker than the tiles or bricks 24, 28. Each tile or brick 26 has a thickness or depth of 220mm and a nominal diameter of 300mm.

20 Each half hexagonal tile or brick 28 has a nominal diameter of 300mm and a depth or thickness of 120mm, which is the same as the depth or thickness of the tiles or bricks 24.

25 As shown in Figures 5 and 7 of the drawings, the tiles or bricks 26, 28 also have circular cylindrical passages 30 extending through them. Each passage has a diameter of 32mm, which is the same as the diameter of the passages 30 extending through the hexagonal tiles or bricks 24. Thus, the bricks or tiles 26, 28 have fewer passages than the bricks or tiles 24, thirteen in the case of the bricks or tiles 26, and seven in the case of the half hexagonal bricks or tiles 28.

In use, hydrocarbon gas, such as methane, is reacted thermally and catalytically with steam and oxygen in the reformer 10 at a temperature of about 800°C to 1300°C to produce synthesis gas which includes CO, H₂ and CO₂. The gas is passed vertically downwardly through the reformer 10, from the open flame reaction zone 14 through the brick or tile layer 22 and the catalyst bed 12. The hydrocarbons are reformed in an open flame in the open flame reaction zone 14 above the brick or tile layer 22, as well as in the catalyst bed 12. However, as the reformer 10, prior to being converted to a reformer which includes an open flame reaction zone 14, included only the catalyst bed 12 and not the open flame reaction zone 14, it has an internal diameter which is relatively small compared to the internal diameter of other reformers designed from the start to operate with an open flame reaction zone as well as a catalyst bed and having the same design throughput as the reformer 10. As a result, higher gas velocities are encountered in the open flame reaction zone 14, as well as in the rest of the converted reformer 10, compared to said other reformers.

In a reformer designed from the start to operate with an open flame reaction zone 14 and a catalyst bed 12, the gas velocity through the reformer is high enough to move catalyst and refractory particles, leading to erosion of the catalyst and erosion of the refractory layer 18. As will be appreciated, this situation is exacerbated by the even higher gas velocities in the converted reformer 10. Erosion products build up in the catalyst bed 12, leading to an increased pressure drop through the catalyst bed 12 and to a lower throughput through the reformer 10. Thus, the purpose of the brick or tile layer 22 is to inhibit movement of the catalyst particles in the catalyst bed 12.

As mentioned above, the gas velocity through the converted reformer 10 is even higher than the gas velocities through reformers which were designed from the start to operate with an open flame reaction zone and a catalyst bed. The high gas velocities cause movement of the catalyst particles and of the original bricks or tiles in the brick or tile layer, if they are retained in

the converted reformer, thus causing erosion of the refractory layer 18. In addition, pieces of the refractory layer 18 above the tile or brick layer 22 and sometimes pieces of the tiles or bricks of the layer 22 break loose and can then be whirled around the inner periphery of the reformer 10, in an annular zone 5 above the tile or brick layer 22, by the gas flowing through the reformer 10. These solid objects typically erode the refractory surface in an annular band extending for a short distance, e.g. about 30cm, above the tile or brick layer 22.

10 The bricks or tiles 24, 26, 28 of the converted reformer 10 are thus larger in plan view and heavier, compared to the original bricks or tiles which were used to make up the brick or tile layer 22 in the reformer 10 prior to the conversion of the reformer 10 in accordance with the invention and immediately after the conversion of the reformer 10 to operate with the open flame reaction zone. This inhibits the moving or lifting of the bricks or tiles owing to the high gas velocity through the converted reformer 10. Furthermore, the bricks or tiles 26 of 15 increased height each define a bay or pocket in which solid objects whirled around the reformer 10 above the layer 22 by the gas passing through the reformer 10 can be trapped, thus inhibiting erosion of the refractory layer 18 above the tile or brick layer 22.

20 It is an advantage of the invention, as illustrated, that it provides a relatively cheap option to inhibit erosion of surfaces of a reformer which has been converted to include an open flame reaction zone, or which is operated above its original design throughput.

CLAIMS:

1. A method of inhibiting erosion of an interior surface of a process vessel by solid objects carried in a fluid passing over the interior surface, the method including providing at least one formation at or in close proximity to the interior surface to interfere with the flow of the fluid over the interior surface, and to interfere with the movement of the solid objects by the fluid.
5
2. A method as claimed in Claim 1, in which the formation traps the solid objects.
3. A method as claimed in Claim 1 or Claim 2, in which at least a portion of the interior surface of the vessel is substantially cylindrical, and in which the fluid follows a whirling flow path, the method including providing a plurality of circumferentially spaced formations at or in close proximity to an annular portion or zone of the interior surface expected to be most affected by erosion.
10
4. A method as claimed in Claim 3, in which the formations are provided in a horizontal plane and in which the formations are equidistantly spaced.
15
5. A method as claimed in Claim 3 or Claim 4, in which the objects are trapped in bays or pockets defined between pairs of formations or between each formation and the interior surface of the vessel, as the case may be.
20
6. A method of inhibiting erosion of an interior refractory surface of a reformer for producing synthesis gas, by solid objects carried in a gas stream passing over the interior refractory surface, the method including providing at least one formation at or in close proximity to the refractory surface in the path

of the objects to interfere with the flow of the gas over the interior surface, and to interfere with the movement of the solid objects by the gas.

7. A method as claimed in Claim 6, in which a plurality of formations are provided and in which each formation traps the solid objects, the objects being trapped in bays or pockets defined between pairs of formations or between each formation and the interior refractory surface, as the case may be.

5 8. A method as claimed in Claim 6, in which the reformer includes a catalyst bed with retaining means, in the form of a generally horizontally extending tile or brick layer configured to allow gas to pass downwardly through the tile or brick layer, on the catalyst bed for retaining the catalyst bed in position 10 in the face of high gas velocities in the reformer, the method including providing a plurality of formations at or in close proximity to the interior refractory surface and above an upper surface of the tile or brick layer.

15 9. A method as claimed in Claim 8, in which the formations are located in an annular band or zone extending from the upper surface of the tile or brick layer to about 30cm above the upper surface of the tile or brick layer.

20 10. A method as claimed in Claim 8 or Claim 9, in which providing a plurality of formations includes placing a plurality of tiles or bricks, each having an increased depth or thickness compared to other tiles or bricks in the layer of tiles or bricks, at spaced peripheral positions in the layer of tiles or bricks, adjacent the interior refractory surface.

25 11. A process vessel which includes a body defining an interior vessel surface; a catalyst bed in the body; retaining means on the catalyst bed for retaining the catalyst bed in position; and

at least one formation at or in close proximity to the interior vessel surface above the retaining means for interfering with fluid flow above the retaining means, which fluid flow can cause fluid-borne solid objects in said flow to erode the interior vessel surface above the retaining means.

5 12. A vessel as claimed in Claim 11, in which the or each formation is arranged to deflect the solid objects away from the interior surface.

13. A vessel as claimed in Claim 11, in which the or each formation is arranged to trap the solid objects.

14. A vessel as claimed in any one of Claims 11 to 13 inclusive, in
10 which the retaining means includes a generally horizontally extending layer of tiles or bricks laid on top of the catalyst bed, the layer of tiles or bricks allowing fluid to pass downwardly through the layer, the vessel including a plurality of spaced formations for interfering with fluid flow above the layer of tiles or bricks, each formation being defined by a tile or brick in the layer having an increased depth or thickness compared to the depth or thickness of other tiles or bricks in the layer.

15. A vessel as claimed in Claim 14, in which the tiles or bricks of increased depth or thickness are located at circumferentially equidistantly spaced peripheral positions in the layer of tiles or bricks.

20 16. A vessel as claimed in Claim 14 or Claim 15, in which some of the tiles or bricks are regular hexagonal in plan view, some are trapezoidal and half of a regular hexagon in plan view, and some are pentagonal shaped in plan view, allowing the tiles or bricks to be laid out next to one another in abutting side by side relationship in a horizontal plane to form a roughly hexagonal plane figure in outline in plan view having extremities which fall on the outline of a hexagon and a circle.

17. A vessel as claimed in any one of Claims 14 to 16 inclusive, in which at least some of the bricks or tiles include a plurality of passages extending therethrough between an opening in a top surface and an opening in a bottom surface of each of said some bricks or tiles, at least 15% of a top surface area of each apertured brick or tile being occupied by the openings of the passages.

5 18. A vessel as claimed in Claim 17, in which the percentage of the top surface area of each apertured brick or tile occupied by the openings is at least 20%, at least some centrally located bricks or tiles having no passages.

10 19. A vessel as claimed in any one of Claims 14 to 18 inclusive, in which a ratio between the depth or thickness of the bricks or tiles having an increased depth or thickness to the depth or thickness of the other bricks or tiles in the layer is between 1,5:1 and 2:1.

15 20. A method of converting a reformer for production of synthesis gas having a catalyst bed but no open flame reaction zone above the catalyst bed, to a reformer having a catalyst bed and an open flame reaction zone above the catalyst bed, the method including providing at least one formation at or in close proximity to an interior refractory surface of the reformer at an elevation at which erosion of the refractory surface of the converted reformer due to gas-borne solid objects is expected, the formation acting to interfere with the flow of the gas over the interior surface, and to interfere with the movement of the solid objects by the gas.

20 21. A method as claimed in Claim 20, in which the formation is configured to trap the gas-borne solid objects.

25 22. A method as claimed in Claim 20 or Claim 21, in which the reformer includes retaining means on the catalyst bed for retaining the catalyst bed in position, the formation being provided so that it interferes with the movement of

solid objects expected to be carried by the gas in a whirling flow path above the retaining means.

23. A method as claimed in Claim 22, in which the retaining means includes a layer of bricks or tiles laid on top of the catalyst bed, the method including replacing at least some of the existing bricks or tiles in the layer with replacement bricks or tiles which are larger in plan view and/or which are heavier, compared to the existing bricks or tiles in the layer.

5 24. A method as claimed in Claim 23, which includes providing a plurality of formations at or in close proximity to the interior refractory surface of 10 the reformer at the elevation at which erosion of the refractory surface due to gas-borne solid objects is expected, each formation being defined by a brick or tile in the layer having an increased depth or thickness compared to the depth or thickness of other tiles or bricks in the layer.

15 25. A method as claimed in Claim 24, in which the tiles or bricks of increased depth or thickness are located at circumferentially equidistantly spaced peripheral positions in the layer of tiles or bricks.

20 26. A method as claimed in Claim 24 or Claim 25, in which all of the existing bricks or tiles in the layer are replaced with replacement bricks or tiles, some of the replacement bricks or tiles being regular hexagonal in plan view, some of the replacement bricks or tiles being trapezoidal and half of a regular hexagon in plan view, and some of the replacement bricks or tiles being pentagonal shaped in plan view, allowing the replacement bricks or tiles to be laid out next to one another in abutting side by side relationship in a horizontal plane to form a roughly hexagonal plane figure in outline in plan view having extremities 25 which fall on the outline of a hexagon and a circle.

27. A method as claimed in Claim 26, in which at least some of the bricks or tiles include a plurality of passages extending therethrough between an opening in a top surface and an opening in a bottom surface of each of said some bricks or tiles, at least 15% of a top surface area of each apertured brick or tile being occupied by the openings of the passages.

5 28. A method as claimed in Claim 27, in which the percentage of the top surface area of each apertured brick or tile occupied by the openings is at least 20%, at least some centrally located bricks or tiles having no passages.

10 29. A method as claimed in any one of Claims 24 to 28 inclusive, in which a ratio between the depth or thickness of the bricks or tiles having an increased depth or thickness to the depth or thickness of the other bricks or tiles in the layer is between 1,5:1 and 2:1.

15 30. A method as claimed in any one of Claims 24 to 29 inclusive, in which a ratio between a nominal diameter and the thickness or depth of each replacement brick or tile of standard depth is between 4:1 and 1:1.

31. A method as claimed in Claim 30, in which the ratio between the nominal diameter and the thickness or depth of each replacement brick or tile of standard depth is between 3:1 and 2:1.

20 32. A method of inhibiting erosion of an interior surface of a process vessel as claimed in Claim 1, substantially as herein described and illustrated.

33. A method of inhibiting erosion of an interior refractory surface of a reformer as claimed in Claim 6, substantially as herein described and illustrated.

34. A process vessel as claimed in Claim 11, substantially as herein described and illustrated.

35. A method of converting a reformer as claimed in Claim 20, substantially as herein described and illustrated.

36. A new method of inhibiting erosion, a new vessel, or a new method of converting a reformer, substantially as herein described.
